Botteri’s Sparrow (Peucaea botterii) Occurs in Northern Coahuila, Mexico

Paul van Els,1,3 Ricardo Canales-del-Castillo,2 and John Klicka1

ABSTRACT.—Botteri’s Sparrow (Peucaea botterii) occurs widely in the shrub-grasslands of southern North America. We report a breeding population of the species in the Sierra de la Encantada of northern Coahuila, Mexico, 80 km from the Big Bend area of Texas and 300 km from the nearest previously known breeding range in southern Coahuila and central Chihuahua. We captured three individuals, which show a mostly gray dorsal coloration, suggestive of the texana subspecies, occurring from southern Texas to northern Veracruz. The exact affinity of the northern Coahuila population still needs to be ascertained. The presence of Botteri’s Sparrow in northern Coahuila may have been overlooked previously or may be part of a (temporary) range expansion. More work is needed to map the occurrence of Botteri’s Sparrow in northcentral Mexico grasslands.

OBSERVATIONS

We surveyed the Valle Colomba ranch in the Sierra de la Encantada of northwestern Coahuila (28° 39' 7.31" N, 101° 20' 16.407" W) on 24–26 June 2010. We found several singing male Botteri’s Sparrows, as well as young lacking tail feathers, a strong indication of local breeding. The Valle de Colombia area consists of lightly grazed montane (1,350 m) native grasslands interspersed with Prosopis spp. (Fabaceae), Koeberlinia spinosa (Koeberlinaceae), Flourensia cernua (Asteraceae), Berberis trifoliolata (Berberidaceae), and local stands of Yucca spp. (Agavaceae). Winter shrub cover (x \pm SD) varied locally from 1.28 \pm 1.12 to 6.68 \pm 5.48% (January 2010). Sparrows were most frequently observed singing from the tops of Prosopis spp. We were able to capture three individuals, two males and a female. Birds were dissected to establish gender. Body mass (x \pm SD) was 19.8 \pm 2.5 g, tarsal length was 20.5 \pm 1.6 mm, wing length was 62.0 \pm 0.6 mm, tail length was 60.6 \pm 0.6 mm, bill length was 10.9 \pm 0.4 mm, bill width was 5.8 \pm 0.2 mm, and bill depth was 5.3 \pm 0.1 mm. Dorsal coloration, the most variable character within the species (Webster 1959), was mostly gray with a profusion of rufous streaks. We deposited a sound recording of a male song from the Sierra de la Encantada in xeno-canto (www.xeno-canto.org, accession number XC57103).

DISCUSSION

Botteri’s Sparrow occurs rarely in southwestern Texas (Bryan 2002), and breeding of the species in northwestern Coahuila constitutes a northward shift in the central part of the known range of the species by \(>300\) km. Northern Coahuila is poorly sampled ornithologically and our records of Botteri’s Sparrow in the Sierra de la Encantada may only represent a fraction of the species’ population in the region. Suitable, intact grassland habitat may be present elsewhere in this area, including potentially Texas, only 80 km from the current population. The occurrence of a small, now possibly extinct population in central Chi-
huahua (Meents 1979), may be an indication that Botteri’s Sparrow is, at least locally, more widespread in northern Mexico than thought. Alternatively, the lack of earlier records of the species may indicate Botteri’s Sparrow occurrence in northern Coahuila is part of a range extension. More work in the region is needed to ascertain whether the Sierra de la Encantada birds represent an isolated population or whether they are part of a discontinuous, but more widespread occurrence in the area.

The dorsal coloration of birds from the Sierra de la Encantada is suggestive of the *texana* subspecies, which ranges from southern Texas to northern Veracruz. The *arizonae* subspecies is distributed from Arizona south to Durango, and presumably includes the central Chihuahuan population. Birds from northern Coahuila may as well belong to the *arizonae* group due to geographical proximity and subtility in plumage differences between subspecies. It is also possible the Sierra de la Encantada population represents an undescribed subspecies. Morphometrics of our birds provided no information for assigning subspecies; male tail length was within the range of both the *texana* and the *arizonae* subspecies and male wing length was typical for *arizonae* and only slightly smaller than for *texana* (Webster 1959). We know of no known consistent vocal differences between subspecies (Webb and Bock 1996).
