ABSTRACT

A Branch and Bound Method for Sum of Completion Permutation Flow Shop

By

Swapna Kodimala

Dr. Wolfgang Bein, Examination Committee Chair

Professor of Computer Science

University of Nevada, Las Vegas

We present a new branch and bound algorithm for solving three machine permutation flow shop problem where the optimization criterion is the minimization of sum of completion times of all the jobs. The permutation flow shop problem (F||∑Ci) belongs to the class of NP-hard problems; finding the optimal solution is thus expected to be highly computational. For each solution our scheme gives an approximation ratio and finds near optimal solutions. Computational results for up to 20 jobs are given for 3 machine flow shop problem when the objective is minimizing the sum of completion times. The thesis also discusses a number of related but easier flow shop problems where polynomial optimization algorithms exist.
ACKNOWLEDGEMENTS

I wish to express my deep gratitude to my advisor and chair, Dr. Wolfgang Bein, for his excellent guidance, supervision and tremendous support. His guidance helped me all the time and his invaluable support during my TA work helped me to complete my thesis.

I would like to specially thank Dr. Laxmi P. Gewali, Dr. Ajoy K. Datta and Dr. Zhiyong Wang for their willingness to serve on my committee.

I am grateful to Dr. Ajoy K. Datta for his moral support and encouragement. I am indebted to school of computer science, University of Nevada Las Vegas for providing the financial support.

Finally I would like to thank my parents, both elder sisters and my dear friends for their endless support and motivation. They were always willing to help me and encourage me with their best wishes.

CHAPTER 1
INTRODUCTION TO SCHEDULING

1.1 Scheduling

A scheduling problem can be described as follows. Given \( m \) identical machines \( M_j (j = 1, 2, ..., m) \) and \( n \) jobs \( J_i (i = 1, 2, ..., n) \) with processing times. A schedule is an optimal allocation of jobs to machines over time. The scheduling restrictions are a job cannot be processed by more than one machine at a time and a machine can process at most one job at a time.

Gantt charts are used to graphically represent a schedule. There are two types of Gantt charts, namely machine oriented Gantt charts and job-oriented Gantt charts. In machine oriented Gantt charts X-axis represents the time and Y-axis represents the machines. In job oriented Gantt charts X-axis represents the time and Y-axis represents the jobs. Figure 1.1 and Figure 1.2 represent the machine oriented and job oriented Gantt chart respectively for 3 machine and 4 jobs problem.

![Figure 1.1 Machine Oriented Gantt Chart](image1.png)

![Figure 1.2 Job Oriented Gantt Chart](image2.png)

1.1.1 Notations

According to Peter Brucker\(^2\), the following notations are used to describe a basic scheduling problem.

\( J_i \) represents the set of \( n \) jobs where \( i = \{1, 2, ..., n\} \). \( M_j \) represents the set of \( m \) machines where...
Each job \( J_i \) has \( k \) number of operations and are denoted as \( O_{i1}, O_{i2}, ..., O_{ik} \). Associated with each operation is a processing time denoted by \( p_{ij} \). Completion time of operation of job \( i \) on machine \( j \) is denoted as \( c_{ij} \). Completion time of job \( J_i \) is the time taken by the job to complete all its operations and is denoted by \( C_i \). In addition each job has a weight \( w_i \), deadline \( d_i \) and release time \( r_i \).

A schedule is said to be feasible if no two operations of a job are processed at the same time and a machine can process at most one job at a time. A schedule is said to be optimal if it minimizes the optimality criteria.

### 1.2 Classes of Scheduling

Scheduling problems are defined by a three field notation \( \alpha|\beta|\gamma \) [2] where

- \( \alpha \) describes machine environment
- \( \beta \) describes job characteristics and
- \( \gamma \) specifies optimality criteria

#### 1.2.1 Machine Environment (\( \alpha \))

The machine environment is described by the string \( \alpha = \alpha_1\alpha_2 \) where \( \alpha_1 \in \{ o, P, Q, R, PMPM, QMPM, G, J, O, F, X \} \) and \( \alpha_2 \) specifies number of machines.

**Case 1:** If \( \alpha_1 \in \{ o, P, Q, R, PMPM, QMPM \} \) each job \( J_i \) consists of a single operation.

- \( \alpha_1 \in o \) **Single machine**

\( o \) represents the empty symbol. When \( \alpha_1 = o, \alpha_2 = \alpha_2 \) and here only single machine is available for processing the jobs.

- \( \alpha_1 \in P \) **Identical parallel machines**

There are \( m \) parallel machines with identical speeds available for processing the jobs. The processing time \( p_{ij} \) of job \( J_i \) on machine \( M_j \) is, \( p_{ij} = p_i \).

- \( \alpha_1 \in Q \) **Uniform parallel machines**

For processing the jobs there are \( m \) parallel machines available with each machine having an individual processing speed \( s_j \). The processing time \( p_{ij} \) of job \( J_i \) on machine \( M_j \) is, \( p_{ij} = p_i / s_j \).

- \( \alpha_1 \in R \) **Unrelated parallel machines**

For processing the jobs there are \( m \) parallel machines available with each machine having an individual processing speed \( s_{ij} \). The processing time \( p_{ij} \) of job \( J_i \) on machine \( M_j \) is, \( p_{ij} = p_i / s_{ij} \).
\( \alpha_1 \in \text{PMPM or QMPM} \)

If \( \alpha_1 = \text{PMPM} \) or \( \text{QMPM} \) then they are multi-purpose machines with identical speeds and uniform speeds respectively.

Case 2: If \( \alpha_1 \in \{ G, J, O, F, X \} \) then each job \( J_i \) is associated with a set of operations \( \{ O_{i1}, O_{i2}, ..., O_{ik} \} \) and each operation must be processed on a dedicated machine.

\( \alpha_1 \in G \ General shop \)

In general shop there is precedence relation between the operations.

\( \alpha_1 \in J \ Job shop \)

Job shop is a special case of general shop. In job shop each job has a predetermined route and the precedence relation between the operations is of the form \( O_{i1} \rightarrow O_{i2} \rightarrow ...... O_{ik} \). Thus for the job shop problem, for each machine \( j \) we need to find a job order.

\( \alpha_1 \in F \ Flow shop \)

In flow shop each job \( J_i \) consists of \( m \) operations \( O_{i1}, O_{i2}, ..., O_{im} \) and the \( j^{th} \) operation of job \( i \) has to be processed on machine \( j \) for \( p_{ij} \) time units. The precedence relation between the operations is, a job can start processing on machine \( j \), only after completing its operation on machine \( (j-1) \). Here all the jobs follow the same machine order \( M_1 \rightarrow M_2 \rightarrow ...... M_m \). Thus for the flow shop problem we need to find the job order for each machine. If all the machines follow the same job order then is called permutation flow shop. For permutation flow shop we use the notation \( F – \text{perm} \).

\( \alpha_1 \in O \ Open shop \)

In open shop each job \( J_i \) consists of \( m \) operations \( O_{i1}, O_{i2}, ..., O_{im} \) and the \( j^{th} \) operation of job \( i \) has to be processed on machine \( j \) for \( p_{ij} \) time units. There are no precedence relations between the operations. Thus in case of open shop we need to find both the job as well as machine orders.

\( \alpha_1 \in X \ Mixed shop \)

Mixed job is the combination of job shop and open shop.

</tr>
</tbody>
</table>

Table 1.1 Notations for Machine Environment (\(\alpha\))

1.2.2 Job Characteristics (\(\beta\))

Job characteristics are specified by the set \(\beta \in \{\beta_1, \beta_2, \beta_3, \beta_4, \beta_5, \beta_6\}\)[2].

\(\beta_1 \in \text{pmtn Preemption}\)

Preemption means that the processing of the jobs can be interrupted and can be resumed later even on other machine. If \(\beta_1 = \text{pmtn}\) then preemption is allowed, otherwise preemptions are not allowed.

\(\beta_2 \in \text{prec Precedence constraints}\)

Job \(J_j\) cannot start processing until the job \(J_i\) has completed. This constraint on jobs is specified using precedence constraints. Precedence constraints are given by graph \(G = (V, A)\) where each vertex corresponds to a job and each arc represents a precedence constraint. Chains, intree, outree, sp-graph gives restricted precedence constraint between the jobs. We set \(\beta_2 = \text{chains}\) if each node has atmost one predecessor and one successor. We set \(\beta_2 = \text{intree}\) if each node has atmost one successor and \(\beta_2 = \text{outree}\) if each node has atmost one predecessor.

According to Peter Brucker[2], A graph \(G = (V, A)\) is called a series parallel graph if it consists of a single vertex or if it is formed by the parallel combination of two graphs \(G1 = (V1, A1)\) and \(G2 = (V2, A2)\) such that \(G = (V1 \cup V2, A1 \cup A2)\) or by the series combination of two graphs.
\( G_1 = (V_1, A_1) \) and \( G_2 = (V_2, A_2) \) such that \( G = (V_1 \cup V_2, A_1 \cup A_2 \cup T_1 \times S_2) \). Here \( T_1 \) is set of sinks in graph \( G_1 \) and \( S_2 \) is set of sources in graph \( G_2 \). We set \( \beta_2 = \text{sp-graph} \) if the given graph is a series parallel graph.

\( \beta_3 \in r, \text{Release dates} \)

Release dates specifies the time when the first operation of the job \( J_i \) is available for processing. If each job is associated with a release time then it is specified by \( \beta_3 = r_i \) [3].

\( \beta_4 \in p_{ij}, \text{Processing times} \)

If there are restrictions on the processing times of the jobs then we represent it using \( \beta_4 \). If \( \beta_4 = p_{ij} = 1 \) then the processing times of all the jobs is 1. If \( \beta_4 = p_{ij} = p \) then the processing times of all the jobs is equal to \( p \).

\( \beta_5 \in d_i, \text{Deadlines} \)

Deadline is the time by which the job \( J_i \) has to complete its execution. If the jobs are subjected to deadline constraint then it is specified by \( \beta_5 = d_i \).

\( B_6 \in \{s\text{-}batch, p\text{-}batch\}, \text{Batch processing} \)

In batch problems the jobs are grouped together and are scheduled. There are two types of batches namely \( s\text{-}batch \) and \( p\text{-}batch \). The completion time of jobs in the batch is equal to finishing time of the batch. In \( s\text{-}batch \) the finishing time of the batch is the sum of processing times of all the jobs in the batch and in \( p\text{-}batch \), the finishing time of the batch is maximum of processing times of jobs.

1.2.3 Optimality Criteria (\( \gamma \))

According to Peter Brucker[3], the third field refers to optimality criteria. A schedule is said to be optimal if it minimizes the objective function. \( c_{ij} \) denotes the completion time of operation of job \( i \) on machine \( j \).

\( C_i \) denotes completion time of job \( J_i \). Completion time of a job is the time at which the job completes its processing and exits the system. The commonly used objectives are to minimize the makespan or the sum of the completion times of the jobs.

**Makespan (Cmax)**

Makespan is the maximum of the completion times of all the jobs. It is represented as \( C_{\text{max}} \).

\[
C_{\text{max}} = \max \{ C_i, i = 1,2, \ldots, n \}
\]
Sum of Completion Time (\( \sum C_i \))

Sum of completion time is the summation of the completion times of all the jobs.

\[
\sum C_i = \sum_{i=1}^{n} C_i
\]

Lateness (\( L_i \))

Lateness is the difference between the completion time of a job and its due date. It is used to determine whether a job is completed before or after its due date. If lateness is positive implies a job is completed after the due date and is called tardiness. If lateness is negative, it is earliness and implies that the job is competed before the due date [3].

\[
L_i = C_i - d_i
\]

Tardiness (\( T_i \))

Tardiness occurs if the job \( J_i \) is completed after its deadline. It is given as,

\[
T_i = \max \{ 0, C_i - d_i \}
\]

Earliness (\( E_i \))

Earliness occurs if the job \( J_i \) is completed before its deadline. It is given as,

\[
E_i = \max \{ 0, d_i - C_i \}
\]

Unit Penalty (\( U_i \))

If a job \( J_i \) is completed after the deadline, then a penalty of one unit is imposed on the job.

\[
U_i = \begin{cases} 
0 & C_i \leq d_i \\
1 & \text{otherwise}
\end{cases}
\]

Absolute Deviation (\( D_i \))

\[
D_i = |C_i - d_i|
\]

Squared Deviation (\( S_i \))

\[
S_i = (C_i - d_i)^2
\]

1.3 Disjunctive Graph Model

Disjunctive graph depicts all the feasible solutions of the shop problems. The feasible solution set always contains the optimal solution. Therefore disjunctive graph model can be used to find the optimal solution. According to Peter Brucker\(^2\), for a disjunctive graph \( G(V, C, D) \)
**V Set of vertices**

$V$ is the set of vertices containing the operations of all jobs. In addition to these vertices, it also contains a source (0) and a sink (*) vertex. Weight of source and sink are zero while the weights of all the other nodes are there corresponding processing times.

**C Set of conjunctive arcs**

$C$ is the conjunctive arc set representing the precedence constraint between the operations. Additionally conjunctive arcs are drawn between source and all operations without a predecessor and between sink and all operations without a successor.

**D Set of disjunctive arcs**

Disjunctive arcs are drawn between pair of operations belonging to the same job which are not connected by conjunctive arcs and between pair of operations which are to be processed on the same machine and which are not connected by conjunctive arcs.
CHAPTER 2
FLOW SHOP SCHEDULING

2.1 Flow Shop Problem

A flow shop problem is defined as follows. There are \( n \) jobs \( J_1, J_2, J_3, \ldots, J_n \) and \( m \) machines \( M_1, M_2, M_3, \ldots, M_m \). Each job \( J_i \) consists of \( m \) operations \( O_{i1}, O_{i2}, \ldots, O_{im} \) and the \( j^{th} \) operation of job \( i \) has to be processed on machine \( j \) for \( p_{ij} \) time units.

The precedence relation between the operations is, a job can start processing on machine \( j \), only after completing its operation on machine \( (j-1) \) [5]. No two operations of a job are processed at the same time and a machine can process at most one job at a time. In flow shop all the jobs follow the same machine order \( M_1 \rightarrow M_2 \rightarrow \ldots \rightarrow M_m \) but the job order for each machine differs. The common objectives are to minimize the makespan or the sum of the completion times of the jobs. Thus for the flow shop problem, for each machine \( j \) we need to find a job order. In case of \( n \)-job \( m \)-machine flow shop problem there exists \((n!)^m\) schedules and finding an optimal schedule in that case is likely hard.

Therefore we restrict our attention to permutation schedules.

Example for Flow Shop Problem

2.2.1 \(F_2||C_{\text{max}}\) and \(F_2||\sum C_i\)

According to Peter Brucker\(^2\), “For the \(F_2||C_{\text{max}}\) and \(F_2||\sum C_i\) problem there exists an optimal schedule in which both the machines process the jobs in the same order”.

Proof: Assume an optimal schedule with the same order for first \(k\) jobs on both machines and \(k<n\).

Let \(i\) be the \(k^{th}\) job, and let \(j\) be the job immediately after job \(i\) on machine 2.

Then we have the optimal schedule as follows:

![Schedule](image)

Figure 2.3 Schedule Representing Same Job Order for First \(k\) Jobs
If we reschedule job \( j \) to the position immediately after job \( i \) on machine 1 and move all jobs scheduled between job \( i \) and job \( j \) by \( p_{j1} \) time units to the right, (we can do this without increasing the completion time of any job on machine 2) we get another optimal schedule[1]. We can continue this pairwise switching of jobs on the machine 1 until the job order of machine 1 matches with machine 2 [6]. Thus for the \( F2\|C_{\text{max}} \) and \( F2\|\sum C_i \) problem there exists an optimal schedule in which both the machines process the jobs in the same order.

2.2.2 \( Fm\|C_{\text{max}} \)

According to Lemma 6.8 \[2\], “For problem \( Fm\|C_{\text{max}} \) optimal schedule exists with the following properties:

(i) The job sequence on the first two machines is the same.

(ii) The job sequence on the last two machines is the same.

For two or three machines, the optimal solution of the flow shop problem is not better than that of the corresponding permutation flow shop. This is not the case if there are more than three machines”.

Proof: The proof of (i) is similar to \( F2\|C_{\text{max}} \).

In case of (ii), from [1], if the job order differs on last two machines; reschedule the jobs on machine \( m \) so that it matches with the order on machine \( m-1 \). We continue this pairwise switching of jobs on the machine \( m \) until the job order of machine \( m \) and machine \( m-1 \) is identical. Therefore when \( m \geq 3 \) the number of sequences reduces from \( (n!)^m \) to \( (n!) \).

But when \( m \geq 3 \) the above property is not true for the sum of completion time of all jobs, \( Fm\|\sum C_i \)

Example:

<table>
<thead>
<tr>
<th>Job</th>
<th>( p_{i1} )</th>
<th>( p_{i2} )</th>
<th>( p_{i3} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( J_1 )</td>
<td>4</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>( J_2 )</td>
<td>1</td>
<td>4</td>
<td>1</td>
</tr>
</tbody>
</table>

Table 2.3 Example to show same job order for \( Fm\|\sum C_i \) does not hold for \( m \geq 3 \)
For same job order $J_2J_1 \sum C_i = C_1 + C_2 = 9 + 10 = 19$

Figure 2.4 Schedule with same job order on last 2-machines

For different job order $\sum C_i = C_1 + C_2 = 7 + 11 = 18$

Figure 2.5 Schedule with different job order on last 2-machines

From Figure 2.4 and Figure 2.5 we see that, if we follow a different job order on the machine 3, we get another schedule where $\sum C_i = C_1 + C_2 = 7 + 11 = 18$. Therefore the above example makes the point that, when $m \geq 3$ property (ii) does not hold for the total completion time, $Fm||\sum C_i$

### 2.3 Johnson’s Algorithm for $F2||C_{max}$ Problem

According to Peter Brucker [2], Johnson’s algorithm finds the optimal schedule for $F2||C_{max}$ problem. The algorithm uses the same job order on both the machines. It constructs two lists $L$ and $R$, where list $L$ contains jobs such that $p_{ij} < p_{i2}$ and list $R$ contains jobs such that $p_{ij} > p_{i2}$. The optimal schedule is constructed by concatenating $T = L$ and $R$ [6].

From the list of unscheduled jobs identify the job with the smallest processing time. If the job with smallest processing time involves machine 1, then concatenate the job at the end of the list $L$. If the job with the smallest processing time involves machine 2 concatenate the job at the beginning of the list $R$. Then delete the job from the list. This process continues on until all jobs have been scheduled. Final schedule is obtained by combining the lists $L$ and $R$. 

---

11
Algorithm 2.1 Johnson’s Algorithm

1. Let \( S = \{ 1, 2 \ldots n \} \) be the list of unscheduled jobs. Let \( L, R \) denote two other lists
2. Find the job \( i \) with minimum processing time i.e \( p_{ij} \)
3. If \( j = 1 \), concatenate job \( i \) at the end of list \( L \)
4. Else concatenate job \( i \) at the beginning of list \( R \)
5. Remove the job \( i \) from the list \( S \).
6. If there is an unscheduled job GO TO step 1
7. Else concatenate \( L \) and \( R \)

Example for \( F_2 || C_{\text{max}} \):

To explain Johnson’s algorithm the following 5 jobs and 2 machines problem has been used.

<table>
<thead>
<tr>
<th>Job ( i )</th>
<th>( p_{1i} )</th>
<th>( p_{2i} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( J_1 )</td>
<td>4</td>
<td>5</td>
</tr>
<tr>
<td>( J_2 )</td>
<td>1</td>
<td>6</td>
</tr>
<tr>
<td>( J_3 )</td>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>( J_4 )</td>
<td>8</td>
<td>1</td>
</tr>
<tr>
<td>( J_5 )</td>
<td>5</td>
<td>6</td>
</tr>
</tbody>
</table>

Table 2.4 Example to Demonstrate Johnson’s \( F_2 || C_{\text{max}} \) Problem

Let \( S = \{ 1, 2 \ldots n \} \), \( L = \{ \} \), \( R = \{ \} \)

<table>
<thead>

</tbody>
</table>

Table 2.5 Execution Steps for Johnson’s \( F_2 || C_{\text{max}} \) problem
Disjunctive Graph for $F_2||C_{max}$

Therefore using Johnson's algorithm the optimal sequence is, $T = \{J_2, J_1, J_5, J_4, J_3\}$

$T=J_2, J_1, J_5, J_4, J_3$

$C_{max}=28$

Figure 2.7 Optimal Schedule for Johnson’s $F_2||C_{max}$ Problem
Disjunctive Graph of Optimal Solution for $F_2||C_{\text{max}}$

![Disjunctive Graph for Optimal Solution for $F_2||C_{\text{max}}$](image)

**Figure 2.8 Disjunctive Graph for Optimal Solution for $F_2||C_{\text{max}}$**

**Lemma 2.3.1**

According to Lemma 6.9 [2], to solve $F_2||C_{\text{max}}$ problem Johnson proposed a rule called Johnson’s rule. If $T$ is the list constructed by the algorithm then, for any two jobs $J_i$ and $J_j$ if

$$\min \{a_i, b_j\} < \min \{a_j, b_i\}$$

then job $J_i$ is scheduled earlier than job $J_j$ in the list $T$.

**Proof:**

Case 1:

If $a_i$ is min, $a_i < \min \{a_j, b_i\}$ then $a_i < b_i$ implies Job $J_i$ belongs to list $L$. If job $J_i$ is added to list $R$ we are done. Otherwise if Job $J_j$ goes into $L$, it appears after $J_i$ because $a_i < a_j$.

Case 2:

If $b_j$ is min, $b_j < \min \{a_i, b_j\}$ then $b_j < b_i$ implies Job $J_j$ belongs to list $R$. If job $J_j$ is added to list $L$ we are done. Otherwise if Job $J_i$ goes into $R$, it appears before $J_j$ because $b_i > b_j$. 

14
Lemma 2.3.2

According to Lemma 6.10 [2], Consider a schedule in which job j is scheduled immediately after job i, then

\[ \min\{ p_{i1}, p_{i2} \} \leq \min\{ p_{j1}, p_{j2} \} \]

implies that i and j can be swapped without increasing the \( C_{\text{max}} \) value.

Proof:

If j is scheduled immediately after i, then we have three possible cases as shown in figure. Let \( w_{ij} \) be the length of the time period from the start of job i to the finishing time of job j. Then,

Case 1:

\[
\begin{array}{cccc}
\text{.........} & i & j & \text{.........} \\
\text{.........} & i & j & \text{.........} \\
\hline
\end{array}
\]

\( w_{ij} \)

\[ Figure \ 2.9 \ \text{Case (a) if j is scheduled immediately after i} \]

For case 1, \( w_{ij} = \max\{ p_{i1} + p_{j1} + p_{j2} \} \)

Case 2:

\[
\begin{array}{cccc}
\text{.........} & i & j & \text{.........} \\
\text{.........} & i & j & \text{.........} \\
\hline
\end{array}
\]

\( w_{ij} \)

\[ Figure \ 2.10 \ \text{Case (b) if j is scheduled immediately after i} \]

For case 2, \( w_{ij} = \max\{ p_{i1} + p_{i2} + p_{j2} \} \)

15
Case 3: \( w_{ij} = \max\{x + p_{i2} + p_{j2}\} \)

For case 3, \( w_{ij} = \max\{x + p_{i2} + p_{j2}\} \)

From case 1, case 2 and case 3, the possible \( w_{ij} \) is,

\[
\begin{align*}
w_{ij} &= \max\{p_{i1} + p_{j2} + p_{j1}, x + p_{i2} + p_{j2}\} + p_{i2} + p_{j1} + \max\{-p_{j1}, -p_{i2}\} \\
&\leq \max\{p_{j1} + p_{i2} + p_{j1}, x + p_{i2} + p_{j2}\} + p_{i1} + p_{j2}
\end{align*}
\]

Similarly \( w_{ji} = \max\{p_{i1} + p_{j2} + \max\{p_{j1}, p_{i2}\}, x + p_{j2} + p_{i2}\} \) if \( i \) is scheduled immediately after \( j \)

According to Lemma 6.10 \cite{2}, we see that

\[
\min\{p_{j1}, p_{i2}\} \leq \min\{p_{i1}, p_{j2}\} \text{ can be written as,}
\]

\[
\max\{-p_{j1}, -p_{i2}\} \leq \max\{-p_{j1}, -p_{i2}\}
\]

Adding \( p_{i1}, p_{i2}, p_{j1}, p_{j2} \) to both sides of the above inequality we get,

\[
\begin{align*}
&\quad\quad p_{i1} + p_{j2} + \max\{-p_{i1}, -p_{j2}\} + p_{i2} + p_{j1} \leq p_{j1} + p_{i2} + \max\{-p_{i1}, -p_{i2}\} + p_{i1} + p_{j2} \\
&\quad\quad = \max\{p_{j1}, p_{i2}\} + p_{i2} + p_{j1} \leq \max\{p_{j1}, p_{i2}\} + p_{i1} + p_{j2} \\
&\quad\quad = w_{ji} \leq w_{ij}
\end{align*}
\]

As, \( w_{ji} \leq w_{ij} \) implies that we can swap \( i \) and \( j \) without increasing \( C_{\text{max}} \) value.

**Theorem 2.3.3**

According to Theorem 6.11 \cite{2}, the list \( L: L(1), L(2), \ldots, L(n) \) constructed by the Johnson’s algorithm for \( F2 || C_{\text{max}} \) problem is optimal

**Proof:**

To prove the above theorem we use the Lemma 2.3.1 and Lemma 2.3.2

Assume that the list \( L \) constructed by the Johnson’s algorithm was not optimal. Let us consider then, an optimal solution \( S \) such that, \( S \) matches with \( L \) as much as possible in the following way \cite{2}:
\[ L(v) = S(v) \text{ for } v = 1, 2, 3, \ldots, (s-1). \]

Let \( L(s) = i \) and \( S(s) = j \). In \( S \), \( i \) is not an immediate successor of \( j \). Let the job \( k \) be schedule between job \( j \) and job \( i \). Thus we have,

\[ L: L(1), L(2), \ldots, L(s-1), i, k, j \]

\[ S: S(1), S(2), \ldots, S(s-1), j, k, i \]

Here all we have to show is that we can swap \( k \) and \( i \) without increasing \( C_{\text{max}} \) value of \( S \). We need to continue swapping until \( S \) matches with \( L \), then we can say that the list \( L \) constructed by Johnson’s algorithm is optimal.

Since \( k \) is not before \( i \) in \( L \), using the Lemma 2.3.1 we say that,

\[ \min\{p_{ki}, p_{ij}\} \geq \min\{p_{1i}, p_{1j}\} \]

Now applying the lemma 2.3.2 to \( S \), we can swap \( k \) and \( i \) without increasing the \( C_{\text{max}} \) value. We continue swapping in \( S \) until, \( S \) matches with \( L \). Thus the list \( L \) constructed by Johnson’s algorithm is optimal.

### 2.4 Johnson’s Algorithm for \( F^2||\sum C_i \) Problem

Johnson’s algorithm gives arbitrarily bad solution for \( F^2||\sum C_i \) problem. From [5], for example let us consider a two machine flow shop problem with \( n \) jobs. The value \( \epsilon \) is considered very small and value \( k \) is very large.

<table>
<thead>
<tr>
<th>Job ( i )</th>
<th>( p_{1i} )</th>
<th>( p_{2i} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( J_1 )</td>
<td>( \epsilon )</td>
<td>( \epsilon )</td>
</tr>
<tr>
<td>( J_2 )</td>
<td>( \epsilon )</td>
<td>( \epsilon )</td>
</tr>
<tr>
<td>( J_3 )</td>
<td>( \epsilon )</td>
<td>( \epsilon )</td>
</tr>
<tr>
<td>( \vdots )</td>
<td>( \vdots )</td>
<td>( \vdots )</td>
</tr>
<tr>
<td>( J_n )</td>
<td>( \epsilon/2 )</td>
<td>( k )</td>
</tr>
</tbody>
</table>

*Table 2.6 Example to Show Johnson’s Algorithm is bad for \( F^2||\sum C_i \) Problem*

Johnson’s algorithm schedules the \( n^{th} \) job first, followed by jobs \( J_1, J_2, \ldots, J_n \).
\[ \sum C_i = C_1 + C_2 + C_3 + \ldots + C_{n-1} + C_n \]
\[ = (\epsilon/2+k)+(\epsilon/2+k+\epsilon)+(\epsilon/2+k+2\epsilon)+\ldots+(\epsilon/2+k+(n-1)\epsilon) \]
\[ = n(\epsilon/2) + nk + (n(n-1)\epsilon)/2 \]
\[ = nk + \epsilon/2(n+n(n-1)) \]

Therefore the solution constructed by this algorithm is arbitrarily bad as \( n \) grows.

The optimal solution for \( F_2||\sum C_i \) problem would schedule the \( n^{th} \) job last

\[ \sum C_i = C_1 + C_2 + C_3 + \ldots + C_{n-1} + C_n \]
\[ = (\epsilon+c)+(\epsilon+c+\epsilon)+\ldots+\ldots+(\epsilon+c+(n-1)\epsilon) \]
\[ = (n(n+3)-1)(\epsilon/2)+k \]
CHAPTER 3
BRANCH AND BOUND ALGORITHM FOR PERMUTATION FLOW SHOP

From this chapter we consider only permutation flow shop $Fm$-perm. This chapter is organized as follows: In the next section we define the problem statement. In section 3.2 we present the branch and bound algorithm; then in section 3.3 we derive the three possible lower bounds. In section 3.4 we introduce the notations used for branch and bound algorithm. In section 3.5 we illustrate the branch and bound algorithm with an example. In section 3.6 we generalize the branch and bound approach when $m \geq 3$.

3.1 Problem Statement

Given a three machine permutation flow shop scheduling problem $F3$-perm, and the objective is to find a permutation schedule that minimizes the sum of the completion time $\sum C_i$ of all the jobs. The three machine flow shop problem $F3$ is defined as follows:

There are $n$ Jobs $J_i (J_1, J_2, J_3, ... J_n)$ and 3 machines $M_1, M_2, M_3$. Each job must be processed on the three machines, first on machine $M_1$, then on $M_2$ and then on $M_3$. The processing times of job $i$ on machine $j$ is denoted as $p_{ij}$. The completion time of job $i$ on machine $j$ is denoted as $c_{ij}$. The completion time of job $J_i$; $C_i$, is the time when its last operation has completed on the last machine $C_i = C_{i3}$.

The problem $F3$-perm||$\sum C_i$ belongs to the class of NP-hard and thus finding the optimal solution is likely hard. We construct a new branch and bound algorithm for solving it. Branch and bound intelligently enumerates permutations of the schedule. This algorithm is obviously an exponential algorithm, but it performs much better in practice than the complete enumeration.

3.2 Using Branch and Bound Algorithm

Given a Problem $P$ and all feasible solutions of the problem $P$ are defined by the set $S$, which is called the solution space for that problem. The problem $P$ is divided into sub problems $S_i$ such that $S_i \subseteq S$ [2]. These sub problems are again divided into smaller sub problems. Thus branching is a recursive process and entire solution space is organized as a tree.

The basic components needed for branch and bound algorithm are:
**Branching Strategy:** Branching strategy divides the solution space $S$ into smaller and smaller subproblems $S_i (i = 1, 2, 3...r)$ such that $S = \bigcup_{i=1}^{r} S_i$.

**Lower Bounding:** Then we apply an algorithm to calculate the lower bound for each sub problem generated in the branching tree.

**Pruning Strategy:** If the lower bound of the sub problem is greater than or equal to upper bound, then this sub problem cannot yield a better solution and we stop branching from the corresponding node and all other nodes that emerge from it in the branching tree.

The principle of branch and bound algorithm is to make an implicit search through all feasible solutions. Branch and bound tree starts with an initial root node where no jobs have been scheduled. Then we try to branch in this tree by trying to fix each of the jobs as the first job in the sequence. The possible branches are $n$ since there are $n$ jobs. Each of these $n$ nodes emanate in to $(n-1)$ branches as there are $(n-1)$ possible jobs that can occupy the second place in the sequence. Thus this is a recursive process.

In branch and bound algorithm, each node represents a partial schedule where $k$ jobs are scheduled in fixed order. Branching from a node consists of taking each of the unallocated jobs in turn and placing it next to the partial schedule. Each of these new partial schedules is then represented by a new node. The lower bound values for each node are then calculated.

![Figure 3.1 General Branch and Bound Search Tree](image-url)
3.3 Lower Bound Calculation:

Each node in the search tree contains a set of jobs \( k \) that are already scheduled and set of jobs that need to be scheduled. Let \( J_i (J_1, J_2, J_3, ..., J_m) \) represents the set of jobs. Suppose we are at a node at which the jobs in the set \( M \subseteq \{1, 2, \ldots, k\} \) are already scheduled in that order; \(|M| = r\). Let \( U \subseteq \{r+1, r+2, \ldots, n\} \) represents the set of unscheduled jobs. Sum of the completion times for this schedule can be divided into,

\[
S = \sum_{i \in M} C_i + \sum_{i \notin M} C_i
\]  

(3.1)

Computing the second sum is very difficult, therefore we estimate its lower bound based on the following assumptions:

3.3.1 Calculation of \( LB_1 \):

1. Every job \( i \notin M \) starts processing on machine 1 without any delay time. That is, after the first job finishes its processing on machine 1, the following job starts immediately without any waiting time.

\[
LB_1 = \sum_{k=r+1}^{n} \left[ \sum_{i \in M} p_{i1} + (n-k+1)p_{ik1} + p_{ik2} + p_{ik3} \right]
\]

Consider the jobs \( r+1, r+2, \ldots, n \) completes its processing without any delay on machine 1.

| \( M_1 \) | 1,1 | 2,1 | \ldots | 1,1 | r+1,1 | r+2,1 | \ldots | k,1 | \ldots | n,1 |
|----------|-----|-----|-------|-----|------|------|-------|-----|------|
| \( M_2 \) | 1,2 | \ldots | r+1,2 | r+2,2 | \ldots | k,2 | \ldots | n,2 |
| \( M_3 \) | 1,3 | \ldots | r+1,3 | r+2,3 | \ldots | k,3 | \ldots | n,3 |

Figure 3.2 Calculation of \( LB_1 \)

\[
LB_1 = C_{r+1} + C_{r+2} + C_{r+3} + \ldots + C_n
\]

\[
C_{r+1} = \sum_{i \in M} p_{i1} + p_{ir+11} + p_{ir+12} + p_{ir+13}
\]

\[
C_{r+2} = \sum_{i \in M} p_{i1} + p_{ir+11} + p_{ir+21} + p_{ir+22} + p_{ir+23}
\]

\[
C_k = \sum_{i \in M} p_{i1} + p_{ir+11} + p_{ir+12} + \ldots + p_{ik1} + p_{ik2} + p_{ik3}
\]
\[ C_n = \sum_{i \in M} p_{i1} + p_{i_{r+1}1} + p_{i_{r+2}1} + \ldots + p_{i_k1} + \ldots + p_{i_{n1}1} + p_{i_{n2}1} + p_{i_{n3}} \]

Therefore, \[ LB_1 = \sum_{k=r+1}^n \left[ \sum_{i \in M} p_{i1} + (n-k+1)p_{i_k1} + p_{i_k2} + p_{i_k3} \right] \]

For \( LB_1 \) schedule the jobs in \( U \) in increasing order of \( p_{i1} \) values.

### 3.3.2 Calculation of \( LB_2 \):

2. Every job \( i \notin M \) starts processing on machine 2 without any delay time. That is, after the first job finishes its processing on machine 2, the following job starts immediately without any waiting time.

The expression \( \max\{C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} \) is a lower bound on the start of first job \( i \notin M \) on machine 2.

\[ LB_2 = \sum_{k=r+1}^n \left[ \max\{C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} + (n-k+1)p_{i_k2} + p_{i_k3} \right] \]

Consider the jobs \( r+1, r+2 \ldots n \) completes its processing without any delay on machine 2.

| \( M_1 \) | \( 1,1 \) | 2,1 | \ldots | \( r,1 \) | \( r+1,1 \) | \( r+2,1 \) | \ldots | \( k,1 \) | \( \ldots \) | \( n,1 \) |
|---|---|---|---|---|---|---|---|---|---|
| \( M_2 \) | 1,2 | \ldots | \( r,2 \) | \( r+1,2 \) | \( r+2,2 \) | \ldots | \( k,2 \) | \( \ldots \) | \( n,2 \) |
| \( M_3 \) | \ldots | \( r+1,3 \) | \( r+2,3 \) | \ldots | \( k,3 \) | \( \ldots \) | \( n,3 \) |

**Figure 3.2 Calculation of \( LB_2 \)**

\[ LB_2 = C_{r+1} + C_{r+2} + C_{r+3} + \ldots \ldots + C_n \]

\[ C_{r+1} = \max\{C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} + p_{i_{r+1}2} + p_{i_{r+1}3} \]

\[ C_{r+2} = \max\{C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} + p_{i_{r+1}2} + p_{i_{r+2}2} + p_{i_{r+2}3} \]

\[ \ldots \]

\[ C_k = \max\{C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} + p_{i_{r+1}2} + p_{i_{r+2}2} + \ldots + p_{i_k2} + p_{i_k3} \]

\[ \ldots \]
\[ C_n = \max\{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + p_{i_{r+1}} + p_{i_{r+2}} + \ldots + p_{i_{k2}} + \ldots + p_{i_{k2}} + p_{i_{k3}} \]

Therefore, \[ LB_2 = \sum_{k=r+1}^{n} \left[ \max\{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + (n-k+1)p_{i_{k2}} + p_{i_{k3}} \right] \]

For \( LB_2 \) schedule the jobs in \( U \) in increasing order of \( p_{i2} \) values.

### 3.3.3 Calculation of \( LB_3 \):

3. Every job \( i \notin M \) starts processing on machine 3 without any waiting time. That is, after the first job finishes its processing on machine 3, the following job starts immediately without any waiting time. The expression \( \max\{ C_{i,3}, \max\{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i1} \} \) is a lower bound on the start of first job \( i \notin M \) on machine 3.

\[ LB_3 = \sum_{k=r+1}^{n} \left[ \max\{ C_{i,3}, \max\{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i1} \} + (n-k+1)p_{i_{k3}} \right] \]

Consider the jobs \( r+1, r+2 \ldots n \) completes its processing without any delay on machine 3.

<td>\ldots</td>
<td>\ldots</td>
<td>r.2</td>
<td>r+1.2</td>
<td>r+2.2</td>
<td>\ldots</td>
<td>k.2</td>
<td>\ldots</td>
<td>n.2</td>
</tr>
<tr>
<td>( M_3 )</td>
<td>l.3</td>
<td>\ldots</td>
<td>r.3</td>
<td>r+1.3</td>
<td>r+2.3</td>
<td>\ldots</td>
<td>k.3</td>
<td>\ldots</td>
<td>n.3</td>
<td></td>
</tr>
</tbody>
</table>

**Figure 3.3 Calculation of \( LB_3 \)**

\[ LB_3 = C_{r+1} + C_{r+2} + C_{r+3} + \ldots + C_n \]

\[ C_{r+1} = \max\{ C_{i,3}, \max\{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i1} \} + p_{i_{r+1}} \]

\[ C_{r+2} = \max\{ C_{i,3}, \max\{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i1} \} + p_{i_{r+1}} + p_{i_{r+2}} \]

\[ C_k = \max\{ C_{i,3}, \max\{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i1} \} + p_{i_{k+1}} + p_{i_{k+3}} + \ldots + p_{i_{k3}} \]

\[ C_n = \max\{ C_{i,3}, \max\{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i1} \} + p_{i_{n+1}} + p_{i_{n+2}} + \ldots + p_{i_{n3}} \]
Therefore, \( LB_3 = \sum_{k=r+1}^{n} \max\{ C_{i_1,3}, \max\{ C_{i_2,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}, \min_{i \in M} p_{i2}\} \} + (n-k+1)p_{i_3,3} \)

For \( LB_3 \) schedule the jobs in \( U \) in increasing order of \( p_{i3} \) values.

Therefore the lower bound is \( \max (LB_1, LB_2, LB_3) \)

From (3.1), we obtain,

\[
S = \sum_{i \in M} C_i + \sum_{i \in M} C_i \\
S = \sum_{i \in M} C_i + \max (LB_1, LB_2, LB_3) \text{ is the cost of the schedule.}
\]

3.4 Parameters of the Algorithm

Input

The input to the algorithm is given in a file, where the first parameter indicates the number of jobs \( n \), second parameter indicates the number of machines \( m \). From the third parameter the processing times of jobs follows. The number in row \( i \) and column \( j \) is the processing time of job \( i \) on machine \( j \).

Notations

Table 3.4 Basic Notations for Branch and Bound Algorithm
**Algorithm 3.1 Branch and Bound**

1. Initialize $Job\_arr = \{J_1, J_2, J_3...J_n\}$

2. Calculate initial $upperbound = \text{sum of completion times of initial feasible schedule}$
   
   $cb\_order = \text{initial feasible schedule}$

3. $sorting\_Jobs()$

4. $generate\_node(fixed\_Jobarr, \text{level})$
   
   a. IF $\text{level} = n$ (i.e. leaf) then current solution = completion time of the schedule.

   If current solution $< upper\_bound$, update upper bound

   b. ELSE
      
      i. CALCULATE the $lowerBound$

      ii. IF $lowerbound \geq upperbound$ THEN prune the node

      ELSE

      CALL $generate\_node(fixed\_Jobarr, \text{level+1})$

      END IF

      END IF

5. Stop

---

**3.5 The Algorithm Illustration**

To evaluate the branch and bound algorithm the following 5 jobs and 3 machines problem has been used.

<table>
<thead>
<tr>
<th>Job</th>
<th>$p_{i1}$</th>
<th>$p_{i2}$</th>
<th>$p_{i3}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>5</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

**Table 3.5 Example to Demonstrate Branch and Bound**
In the above table, each row represents the job $i$ and each column represents the machine $j$. The processing time of an operation of job $i$ on machine $j$ is mentioned in each cell and is denoted as $p_{ij}$. Our objective is to obtain a permutation schedule that minimizes the sum of completion times of all the jobs.

Step 1: Find initial feasible schedule by arranging the jobs in the increasing order of their sum of processing times. The initial feasible schedule is $[1, 2, 4, 3]$.

<table>
<thead>
<tr>
<th>Job $i$</th>
<th>Sum of $p_{ij}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4+1+1 = 6</td>
</tr>
<tr>
<td>2</td>
<td>2+3+2 = 7</td>
</tr>
<tr>
<td>3</td>
<td>6+5+1 = 12</td>
</tr>
<tr>
<td>4</td>
<td>5+1+3 = 9</td>
</tr>
</tbody>
</table>

Table 3.6 Calculating Initial Feasible Schedule

Step 2: Calculate initial upper bound which is sum of completion times of initial feasible schedule.

For order $[1, 2, 4, 3]$ upper bound (UB) = $\sum_{i=1}^{n} C_i = 6+11+15+23 = 55$

<table>
<thead>
<tr>
<th>Job $i$</th>
<th>$c_{1i}$</th>
<th>$c_{2i}$</th>
<th>$c_{3i}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4</td>
<td>5</td>
<td>6</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>9</td>
<td>11</td>
</tr>
<tr>
<td>4</td>
<td>11</td>
<td>12</td>
<td>15</td>
</tr>
<tr>
<td>3</td>
<td>17</td>
<td>22</td>
<td>23</td>
</tr>
</tbody>
</table>

Table 3.6 Calculating Initial Upper Bound

Step 3: We now compute the lower bound for each node in the tree. In tree each node represents a partial sequence $S_k$ where jobs in the first $k$ positions are fixed. $C_1(k), C_2(k), C_3(k)$, be the completion times on machine 1, machine 2, machine 3 respectively for the partial sequence.

**Calculating Lower Bound for Partial Sequence $[1 * *]$**

Set of scheduled jobs $M = \{1\}$ and $|M| = r = 1$

Set of unscheduled jobs $U = \{2, 4, 3\}$. 

26
Cost of the schedule $S = \sum_{i \in M} C_i + \max \{ LB_1, LB_2, LB_3 \}$

<table>
<thead>
<tr>
<th>Job $i$</th>
<th>$C_1$</th>
<th>$C_2$</th>
<th>$C_3$</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4</td>
<td>5</td>
<td>6</td>
</tr>
</tbody>
</table>

Table 3.8 Calculation of Completion Times for Partial Sequence [1 * * *]

For $LB_1$ from the list of unscheduled jobs $U$, schedule the jobs in the increasing order of their processing times on machine 1. Sequence of jobs with increasing $p_{i1}$ values is [2, 4, 3]. Let $i_k, k = 1, 2, \ldots, n$ be the index of these jobs.

$LB_1 = \sum_{k=r+1}^n \sum_{i \in M} (p_{i1} + (n-k+1)p_{i1} + p_{i2} + p_{i3}) = 15 + 18 + 16 = 49.$

For $LB_2$ from the list of unscheduled jobs $U$, schedule the jobs in the increasing order of their processing times on machine 2. Sequence of jobs with increasing $p_{i2}$ values is [4, 2, 3]. The expression, $\max\{ C_{i2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} = \max \{ 5, 4 + p_{22} \} = \max \{ 5, 4 + 2 \} = 6$

<table>
<thead>
<tr>
<th>$(n-k+1)p_{i2}$</th>
<th>$p_{i3}$</th>
<th>$\max{ C_{i2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} } + (n-k+1)p_{i2} + p_{i3} }$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$k=2$</td>
<td>3</td>
<td>$P_{43} = 3$</td>
</tr>
<tr>
<td>$k=3$</td>
<td>2</td>
<td>$P_{23} = 2$</td>
</tr>
<tr>
<td>$k=4$</td>
<td>1</td>
<td>$P_{33} = 1$</td>
</tr>
</tbody>
</table>

Table 3.9 Calculation of $LB_1$ for Partial sequence [1 * * *]

Table 3.10 Calculation of $LB_2$ for Partial sequence [1 * * *]

27
\[ LB_3 = \sum_{k=r+1}^{n} \left[ \max \{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + (n-k+1)p_{i,k} + p_{i,k,3} \right] = 12 + 14 + 12 = 38 \]

For \( LB_3 \) from the list of unscheduled jobs \( U \), schedule the jobs in the increasing order of processing times on machine 3. Sequence of jobs with increasing \( p_{i3} \) values is [3, 2, 4]. The expression,

\[
\max \{ C_{i,3}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i2} = \max \{ 6, \max \{ 5, 4 + p_{21} \} + p_{42} \}
\]

\[ = \max \{ 6, \max \{ 5, 4 + 2 \} + 1 \} = \max \{ 6, 6 + 1 \} = 7 \]

<table>
<thead>
<tr>
<th>( k )</th>
<th>( (n-k+1)p_{i,k,3} )</th>
<th>( \max { C_{i,3}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} } + \min_{i \in M} p_{i2} )</th>
<th>( (n-k+1)p_{i,k} + p_{i,k,3} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>3.p_{33} = 3</td>
<td>10</td>
<td>10</td>
</tr>
<tr>
<td>3</td>
<td>2.p_{23} = 4</td>
<td>11</td>
<td>11</td>
</tr>
<tr>
<td>4</td>
<td>1.p_{43} = 3</td>
<td>10</td>
<td>10</td>
</tr>
</tbody>
</table>

Table 3.11 Calculation of \( LB_3 \) for Partial sequence [1 ** *]

\[ LB_3 = \sum_{k=r+1}^{n} \left[ \max \{ C_{i,3}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i2} \} + (n-k+1)p_{i,k,3} \right] = 10 + 11 + 10 = 31 \]

\[ LB(1 ** *) = \sum_{i \in M} C_i + \max (LB_1, LB_2, LB_3) = C_i + \max (49, 38, 31) = 6 + 49 = 55 \]

Since lower bound of partial sequence (1 ** *) = 55 ≥ upper bound, prune the node [1**] and all the branches that emerge from it.

**Calculating Lower Bound for Partial Sequence [2 * *]**

Similarly we calculate the lower bound for partial sequence (2 * * )

Set of scheduled jobs \( M = \{ 2 \} \) and \( |M| = r = 1 \)

Set of unscheduled jobs \( U = \{ 1, 4, 3 \} \).

<table>

<td>1, $p_{31} = 6$</td>
<td>$p_{31} = 5$</td>
<td>$p_{33} = 1$</td>
<td>14</td>
</tr>
</tbody>
</table>

Table 3.13 Calculation of $LB_1$ for Partial sequence [2 * * *]

$$LB_1 = \sum_{k=r+1}^{n} \left[ \sum_{i \in M} p_{i1} + (n-k+1)p_{i1} + p_{i2} + p_{i3} \right] = 16 + 16 + 14 = 46.$$  

For $LB_2$ from the list of unscheduled jobs $U$, schedule the jobs in the increasing order of their processing times on machine 2. Sequence of jobs with increasing $p_{i2}$ values is [1, 4, 3]. The expression, $\max\{C_{i2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} = \max\{5, 2 + p_{i1}\} = \max\{5, 2 + 4\} = 6$

<table>
<thead>
<tr>
<th>$k$</th>
<th>$(n-k+1)p_{i2}$</th>
<th>$p_{i3}$</th>
<th>$\max{C_{i2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}} + (n-k+1)p_{i2} + p_{i3}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$k=2$</td>
<td>3, $p_{12} = 3$</td>
<td>$p_{43} = 1$</td>
<td>10</td>
</tr>
<tr>
<td>$k=3$</td>
<td>2, $p_{42} = 2$</td>
<td>$p_{23} = 3$</td>
<td>11</td>
</tr>
<tr>
<td>$k=4$</td>
<td>1, $p_{32} = 5$</td>
<td>$p_{33} = 1$</td>
<td>12</td>
</tr>
</tbody>
</table>

Table 3.14 Calculation of $LB_2$ for Partial sequence [2 * * *]

$$LB_2 = \sum_{k=r+1}^{n} \left[ \max\{C_{i2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} + (n-k+1)p_{i2} + p_{i3} \right] = 10 + 11 + 12 = 33$$

For $LB_3$ from the list of unscheduled jobs $U$, schedule the jobs in the increasing order of processing times on machine 3. Sequence of jobs with increasing $p_{i3}$ values is [1, 3, 4]. The expression,

$$\max\{C_{i3}, \max\{C_{i2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} + \min_{i \in M} p_{i1}\} = \max\{7, \max\{5, 2 + p_{i1}\} + p_{i2}\}$$

$$= \max\{7, \max\{5, 2 + 4\} + 1\} = \max\{7, 6 + 1\} = 7$$
\[
LB_3 = \sum_{k=r+1}^{n} \max\{ C_{i,3} , \max\{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i2} \} + (n - k + 1)p_{ik,3} \]

\[
LB(2 * * *) = \sum_{i \in M} C_i + \max (LB_1, LB_2, LB_3) = C_2 + \max( 46, 33, 29) = 7 + 46 = 53
\]

Since lower bound of partial sequence \((2 * * *)\) = 53 < upper bound, we branch to lower level nodes from partial sequence \((2 * * *)\). Branching from a node consists of taking each of the unallocated jobs in turn and placing it next to the partial schedule. Each of these new partial schedules is then represented by a new node.

**Calculating Lower Bound for Partial Sequence [2 1 *]**

Lower bound for the partial sequence [2 1 *] is calculated as follows:

Set of scheduled jobs \(M = \{2, 1\}\) and \(|M| = r = 2\)

Set of unscheduled jobs \(U = \{4, 3\}\).

<table>
<thead>
<tr>
<th>Job i</th>
<th>(C_1)</th>
<th>(C_2)</th>
<th>(C_3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2</td>
<td>5</td>
<td>7</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>7</td>
<td>8</td>
</tr>
</tbody>
</table>

**Table 3.16 Calculation of Completion Times for Partial sequence [2 1 *]**

For \(LB_1\) from the list of unscheduled jobs \(U\), schedule the jobs in the increasing order of their processing times on machine 1. Sequence of jobs with increasing \(p_{i1}\) values is [4, 3].
Table 3.17 Calculation of $LB_1$ for Partial sequence [2 1 **]

\[
LB_1 = \sum_{k=r+1}^{n} \left( \sum_{i \in M} p_{i1} + (n-k+1)p_{ik1} + p_{ik2} + p_{ik3} \right) = 20 + 18 = 38
\]

For $LB_2$ from the list of unscheduled jobs $U$, schedule the jobs in the increasing order of their processing times on machine 2. Sequence of jobs with increasing $p_{i2}$ values is [4, 3]. The expression,

\[
\max\{C_{i2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} = \max\{7, 6 + p_{41}\} = \max\{5, 6 + 5\} = 11
\]

Table 3.18 Calculation of $LB_2$ for Partial sequence [2 1 **]

\[
LB_2 = \sum_{k=r+1}^{n} \left[ \max\{C_{i2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} + (n-k+1)p_{ik2} + p_{ik3} \right] = 16 + 17 = 33
\]

For $LB_3$ from the list of unscheduled jobs $U$, schedule the jobs in the increasing order of processing times on machine 3. Sequence of jobs with increasing $p_{i3}$ values is [3, 4]. The expression,

\[
\max\{C_{i3}, \max\{C_{i2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1}\} + \min_{i \in M} p_{i2}\} = \max\{8, \max\{7, 6 + p_{41}\} + p_{42}\}
\]

\[= \max\{8, \max\{7, 6 + 5\} + 1\} = \max\{8, 12\} = 12
\]

Table 3.19 Calculation of $LB_3$ for Partial sequence [2 1 **]
\[ LB_3 = \sum_{k=r+1}^{n} \max\{ C_{i,3}, \max\{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i2} \} + (n-k+1)p_{i,3} \] = 14+15 = 29

LB(2 1 ** ) = \sum_{i \in M} C_i + \max (LB_1, LB_2, LB_3) = C_2 + C_1 + \max (38, 33, 29) = 15 + 38 = 53

Since lower bound of partial sequence (2 1 ** ) = 53 < upper bound, we branch to lower level nodes from partial sequence (2 1 * * ). Branching from a node consists of taking each of the unallocated jobs in turn and placing it next to the partial schedule. Each of these new partial schedules is then represented by a new node.

**Calculating Lower Bound for Partial Sequence [2 1 4 *]**

Lower bound for the partial sequence [2 1 4 *] is calculated as follows:

Set of scheduled jobs \( M = \{2, 1, 4\} \) and \( |M| = r = 3 \)

Set of unscheduled jobs \( U = \{3\} \)

Table 3.23 Calculation of $LB_3$ for Partial sequence \([2 \ 1 \ 4 \ *)\]

$$LB_3 = \sum_{k=r+1}^{n} \left[ \max \{ C_{i,3}, \max \{ C_{i,2}, \sum_{i \in M} p_{i1} + \min_{i \in M} p_{i1} \} + \min_{i \in M} p_{i2} \} + (n-k+1)p_{ik3} \right] = 23$$

$$LB(2 \ 1 \ 4 \ *) = \sum_{i \in M} C_i + \max \{ LB_1, LB_2, LB_3 \} = C_2 + C_1 + C_4 + \max( 23, 23, 23 ) = 7 + 8 + 15 + 23 = 53$$

Since lower bound of partial sequence \((2 \ 1 \ 4 \ *)\) = 53 < upper bound, we branch to lower level nodes from partial sequence \((2 \ 1 \ 4 \ *)\). Here when we branch to the lower level, we find that the node with partial sequence \((2 \ 1 \ 4 \ 3)\) is a leaf node, so we calculate the completion time of the schedule.
Table 3.24 Calculation of $\sum C_i$ for Schedule [2 1 4 3]

</tbody>
</table>

Completion time for the schedule [2 1 4 3] = 53 < upper bound. Therefore, now we update the upper bound and the current best order. We now explore other nodes in the search tree with the updated upper bound.

Similarly the lower bound for the partial sequence [2 1 3 *] = 54, [2 4 * *] = 54, [2 3 * *] = 56, [3 * * *] = 60 and [4 * * *] = 57. Since all lower bounds ≥ upper bound (53), we prune all these nodes.

#### Figure 3.3 Screenshot of the Output for the $p_{ij}, p_{i2}, p_{i3}$ Values Given in Table 3.5

3.6 Branch and Bound $Fm$-$perm||\sum C_i$ ($m \geq 3$)

Branch and bound approach for $F3$-$perm||\sum C_i$ can be generalized to $m$ machines. In this case at each node we determine $m$ machine based lower bounds and the overall lower bound is the maximum of the $m$-lower bounds [8].
Thus the lower bound at node T is,

\[ \text{LB} [T] = \sum_{i \in M} C_i + \sum_{i \not\in M} C_i \]

\[ = \sum_{i \in M} C_i + \max (\text{LB}_1, \text{LB}_2, \text{LB}_3... \text{LB}_m) \]

Generally to calculate the lower bound on a machine \( x \), we assume the possibility that the processing on machine \( x \) is continuous for the unassigned job set \( \{ U \} \).

\( \text{LB}_x = \) earliest time that the first job in the set \( U \) can start on machine \( x \) + sum of completion times of jobs in set \( U \) on machine \( x \) (here schedule the jobs in the increasing order of processing times on machine \( x \). Let \( r+1, r+2,...,n \) represent the sequence of jobs with increasing \( p_{i,x} \) values \) + sum of processing times of jobs in set \( U \) on remaining \((m-x)\) machines.

Let \( r \) be the last job in the ordered set of scheduled jobs \( M \), then

\[ \text{LB}_x = \max \{ C_{r,x}, \max_{1 \leq y \leq x-1} \left\{ C_{r,y} + \min_{i \in M} \left( \sum_{j=y}^{x-1} p_{i,k,j} \right) \right\} \} + \sum_{k=r+1}^{n} (n-k+1)p_{i,x} + \sum_{k=r+1}^{n} \sum_{j=x+1}^{m} p_{i,k,j} \]
CHAPTER 4

RESULTS

This chapter gives a detailed view of the results obtained by applying Branch and Bound algorithm for permutation $F3$-$perm||\sum C_i$ scheduling problem.

4.1 Assumptions

Following assumptions are made while implementing the algorithm:

1. The algorithm initializes the branch and bound tree with an initial feasible schedule and an initial upper bound. Initial feasible schedule is obtained by arranging the jobs in the increasing order of their sum of processing times.

2. Initial Upper bound can be obtained by calculating the sum of completion times of initial feasible schedule.

4.2 Parameters that Determine Performance of the Algorithm

Initial Upper Bound

Initial Upper bound is obtained by calculating the sum of completion times of initial feasible schedule.

Global Lower bound

The minimum lower bound on the highest level nodes corresponds to global lower bound. We start the branch and bound tree with initial upper bound. Then we try to branch in this tree by trying to fix each of the jobs as the first job in the sequence. From the data given in Table 3.5 and Figure 3.2, there are four jobs, so possible branches are four.

![Figure 4.1 Branching Tree Showing the Highest Level Nodes](image-url)
Then we calculate the lower bound for these nodes. The minimum lower bound on these highest level nodes corresponds to the global lower bound because all the corresponding branches emerging from these nodes have lower bound greater than or equal to it. For the above problem, global lower bound $= 53$.

**Current Best Solution**

Cost of the schedule obtained by applying branch and bound algorithm represents the current best solution.

**Performance Ratio**

$$\text{% increase over the optimal solution} = \frac{\text{Current best solution}}{\text{Global LB}} \times 100$$

% increase over the optimal solution is used to analyze the performance of branch and bound algorithm. Branch and bound is one of the heuristic to determine near optimal solution, but it does not guarantee to provide an optimal solution. Therefore we use performance ratio in order to determine the percentage of deviation of current best solution obtained from optimal.

**Execution Time**

Execution time is the time taken by the branch and bound program to determine the current best solution. From the above results we see that, branch and bound performs much better in practice than the complete enumeration.

**Number of Eliminated Sequences**

If the lower bound of the sub problem is greater than or equal to upper bound, then this sub problem cannot yield a better solution and we stop branching from the corresponding node in the branching tree. Thus we prune all the branches emerging from that node.

If there are $n$ jobs and if a node at $k^{th}$ level is pruned, then we eliminate $(n-k)!$ sequences from processing.

**4.3 Results for Various $p_{i1}, p_{i2}$ and $p_{i3}$ Values**

Following results are obtained by applying branch and bound algorithm. Computational results for up to 20 jobs are given for 3 machine permutation flow shop problem when the objective is minimizing the sum of completion times.
4.3.1 Random $p_{i1}, p_{i2}$ and $p_{i3}$ Values

For randomly chosen $p_{i1}$, $p_{i2}$ and $p_{i3}$ values given in the Table 4.1 the results obtained by executing branch and bound algorithm for the objective function $\sum C_i$ are presented in Table 4.2 and Table 4.3.

Table 4.9 $\sum C_i$ Results for $p_{i1}, p_{i3}$ Increasing and then Decreasing
4.4 Efficiency of the Algorithm

In order to validate practically the efficiency of branch and bound algorithm, the results of the algorithm are compared with the results obtained by generating all the $n!$ permutations sequences, when number of jobs ($n \leq 12$). From the results obtained, we see that branch and bound performs much better in practice than the complete enumeration. From the experiments, we notice that instead of searching entire solution space branch and bound algorithm pruned many nodes and this considerably reduced the computational time.

Branch and bound algorithm is used to determine near optimal solution, but it does not guarantee to provide an optimal solution. Therefore we use performance ratio in order to determine the percentage of deviation of branch and bound solution from optimal. From the results obtained we see a difference of approximately 1.1% between the branch and bound solution and optimal solution.
CHAPTER 5
CONCLUSION AND FUTURE WORK

In this thesis, we have presented, evaluated and implemented the branch and bound algorithm to minimize the sum of completion times for three machine permutation flow shop problem. We presented the lower bounds, upper bounds and performance ratio for the various problems. In general, our results consistently give solutions with a ratio of better than 1.1% of optimal. We indeed observed that a significant number of sub problems can be eliminated from further consideration, if the initial upper bound is tight. Therefore we can use some good heuristics to obtain better initial upper bound.

As $n$ grows, the branch and bound algorithm is obviously exponential in time but performs much better in practice than the complete enumeration. The future work would be to improve lower bounds for minimizing the sum of completion times of $n$ jobs over $m$ machines.
